Аннотация

Мы приводим новое доказательство теоремы Б. М. Бредихина, которая изначально была доказана путем адаптации решения проблемы Харди-Литтлвуда, полученного Линником с помощью его дисперсионного метода.

Ключевые слова: простые числа, дисперсия, теорема Бомбьери-Виноградова.

Библиография: 5 названий.

Abstract

We give a new proof of a theorem of B. M. Bredihin which was originally proved by extending Linnik's solution, via his dispersion method, of a problem of Hardy and Littlewood.

Keywords: primes, dispersion, Bombieri-Vinogradov theorem.

Bibliography: 5 titles.

1. Introduction

Among the many beautiful consequences of Linnik's dispersion method is an asymptotic formula for the number of solutions to the equation

$$p = a^2 + b^2 + 1$$

in primes $p \leq x$ and integers a and b . This result of 1965, due to Bredihin [2] was a follow-up to Linnik's celebrated work on the Hardy-Littlewood problem, cf. Chapter 7 of [5]. The involved arguments are lengthy and complicated, though very inventive. Due to much progress over the intervening years, much shorter arguments can now be put forward. This of course does not mean that they are shorter ab-initio. Our purpose here is to illustrate how these arguments can be applied.

THEOREM 1. *Let $S(x)$ be the number of solutions to*

$$p = a^2 + b^2 + 1 \tag{1}$$

in integers a and b and primes $p \equiv 3 \pmod{8}$, $p \leq x$. We have

$$S(x) = c \frac{x}{\log x} + O\left(x \left(\frac{\log \log x}{\log x}\right)^2\right), \tag{2}$$

where the constant c is given by

$$c = \frac{\pi}{2} \prod_p \left(1 + \frac{\chi(p)}{p(p-1)}\right), \tag{3}$$

with χ being the Dirichlet character of conductor 4.

The other reduced residue classes modulo 8 can be covered by essentially the same arguments but we do not treat them.

Note that the theorem shows that the integers $p-1$ tend to have about as many representations as the sum of two squares as does a typical integer n . Recall also that, if the number of representable $p-1$ is counted without multiplicity in a and b , then the order of magnitude is given by $x/(\log x)^{3/2}$ by a theorem of the second-named author [4].

2. Dirichlet divisor switching

Let $\lambda = 1 * \chi$ that is

$$\lambda(n) = \sum_{ab=n} \chi(a) \tag{4}$$

This is similar in many respects to the divisor function $\tau(n)$. The number of representations of n as the sum of two squares is equal to $4\lambda(n)$. If $n \equiv 1 \pmod{4}$ then, in (4), $\chi(a)$ can be replaced by $\chi(b)$; therefore we can write

$$\lambda(n) = \sum_{\substack{a|n \\ a \leq y}} \chi(a) + \sum_{\substack{b|n \\ b < n/y}} \chi(b) \tag{5}$$

for any $y > 0$. We can refine this partition by integrating over y against a smooth weight function. Let $w(t)$ be a smooth function supported on $1 \leq t \leq 2$ such that

$$\int_0^\infty w(t) t^{-1} dt = 1. \tag{6}$$

Let $Y \geq 1$, multiply (5) by $w(y/Y)$ and integrate with the measure $y^{-1}dy$, getting

$$\lambda(n) = \int_0^\infty \left[w\left(\frac{y}{Y}\right) + w\left(\frac{n}{yY}\right) \right] \left(\sum_{\substack{b|n \\ b < y}} \chi(b) \right) \frac{dy}{y}. \quad (7)$$

Note that if $X < n \leq 2X$ we can choose $Y = \sqrt{X}$ so the integration in (7) runs over the segment $\frac{1}{2}\sqrt{X} < y < 2\sqrt{X}$.

3. Primes in arithmetic progressions

The key input which greatly streamlines the proof is the main result of [1] which gives asymptotics of Bombieri-Vinogradov type for the distribution of primes in arithmetic progressions and which treats moduli of the progression which go beyond the range of that which can be successfully handled even on the assumption of the Generalized Riemann Hypothesis.

We state this restricted to a range somewhat lesser than that in [1], which is however sufficient for our needs and is conveniently recorded as Theorem 2.2.1 of [3].

$$\sum_{\substack{q \leq Q \\ (q,a)=1}} \left| \pi(x; q, a) - \frac{\pi(x)}{\varphi(q)} \right| \ll x \left(\frac{\log \log x}{\log x} \right)^2 \quad (8)$$

for $Q = \sqrt{x}(\log x)^A$ with any $a \neq 0$, $A \geq 0$, $x \geq 3$, the implied constant depending only on a and A .

We actually require a slightly modified form of (8) which follows from it in two easy steps. In the first place we have

$$\sum_{\substack{q \leq Q \\ (q,a)=1 \\ (q,k)=1}} \left| \sum_{\substack{p \leq x \\ p \equiv a \pmod{q} \\ p \equiv \ell \pmod{k}}} 1 - \frac{\pi(x)}{\varphi(qk)} \right| \ll x \left(\frac{\log \log x}{\log x} \right)^2 \quad (9)$$

for $Q = \sqrt{x}(\log x)^A$ with any $a \neq 0$, $k \geq 1$, $(\ell, k) = 1$, $A \geq 0$, $x \geq 3$, the implied constant depending only on a, k and A . To this end one merely splits the indexed variables into classes modulo k , which is harmless for k fixed.

In the second step we modify (9) to a counting of primes with smooth weight.

LEMMA 1. *Let $f(t)$ be a smooth function supported on $1 \leq t \leq 2$. We have*

$$\sum_{\substack{q \leq Q \\ (q,a)=1 \\ (q,k)=1}} \left| \sum_{\substack{p \leq x \\ p \equiv a \pmod{q} \\ p \equiv \ell \pmod{k}}} f\left(\frac{p}{X}\right) - \frac{1}{\varphi(qk)} \sum_p f\left(\frac{p}{X}\right) \right| \ll x \left(\frac{\log \log x}{\log x} \right)^2 \quad (10)$$

for $Q = \sqrt{x}(\log x)^A$ with any $a \neq 0$, $k \geq 1$, $(\ell, k) = 1$, $A \geq 0$, $x \geq 3$, the implied constant depending only on a, k , A and f .

Proof. We write

$$f\left(\frac{p}{X}\right) = - \int_{p/X}^\infty f'(t) dt.$$

Given $1 \leq t \leq 2$ this implies $p \leq tX$. Applying (9) with $x = tX$ and integrating the result over t , we derive (10). ■

4. Proof of the theorem

We have

$$S(x) = 4 \sum_{\substack{p \leq x \\ p \equiv 3 \pmod{8}}} \lambda\left(\frac{p-1}{2}\right). \quad (11)$$

We are going to evaluate

$$T(X) = S(2X) - S(X) = 4 \sum_{\substack{X < p \leq 2X \\ p \equiv 3 \pmod{8}}} \lambda\left(\frac{p-1}{2}\right) \quad (12)$$

for every $X \geq 3$. Applying (7) we write

$$T(X) = 4 \int \sum_{b < y} \chi(b) \sum_{\substack{X < p \leq 2X \\ p \equiv 1 \pmod{b} \\ p \equiv 3 \pmod{8}}} \left[w\left(\frac{y}{Y}\right) + w\left(\frac{p-1}{2yY}\right) \right] \frac{dy}{y}$$

where we choose $Y = \sqrt{X}$. Here we can replace $w((p-1)/2yY)$ by $w(p/2yY)$ up to an error term $O(1/yY)$ which contributes to $T(X)$ a bounded amount:

$$T(X) = 4 \int \sum_{b < y} \chi(b) \sum_{\substack{X < p \leq 2X \\ p \equiv 1 \pmod{b} \\ p \equiv 3 \pmod{8}}} \left[w\left(\frac{y}{Y}\right) + w\left(\frac{p}{2yY}\right) \right] \frac{dy}{y} + O(1).$$

Note that the integration runs over the segment $\frac{1}{4}\sqrt{X} < y < 2\sqrt{X}$. Now we can apply (9) for the first term and (10) for the second term with $q = b$, $k = 8$, $\ell = 3$, getting

$$T(X) = \int \sum_{b < y} \frac{\chi(b)}{\varphi(b)} \sum_{X < p \leq 2X} \left[w\left(\frac{y}{Y}\right) + w\left(\frac{p}{2yY}\right) \right] \frac{dy}{y} + O\left(X \left(\frac{\log \log X}{\log X}\right)^2\right).$$

Next, we replace the sum over $b < y$ by the complete series

$$c_1 = \sum_b \frac{\chi(b)}{\varphi(b)} = L(1, \chi) \prod_p \left(1 + \frac{\chi(p)}{p(p-1)}\right) \quad (13)$$

up to an error term $O(1/y)$ which contributes to $T(X)$ at most $O(\sqrt{X}/\log X)$. Now the free integration over y yields (see (6))

$$\int \left[w\left(\frac{y}{Y}\right) + w\left(\frac{p}{2yY}\right) \right] \frac{dy}{y} = 2.$$

Therefore,

$$T(X) = 2c_1 (\pi(2X) - \pi(X)) + O\left(X \left(\frac{\log \log X}{\log X}\right)^2\right).$$

Summing this over $X = 2^{-n}x$, $n = 1, 2, 3, \dots$, we derive (2).
